

In the ReadFile method, the program gets the right file. Then it creates a list. After that we make a string called line that contains the value of each line in the text file. In the while loop the program adds all the lines that contains a value into the list. Then it writes the lines into the console.

In the ChangeStats method, we declare some variables that we could change the text file with. We make a string called lines and give it a maximum array size. Then we change the value of each line to the new value. In the for loop we write those lines in the text file.
